### Simulating turbulence

Turbulence: an ancient problem

Simulation of turbulence

Lifecycle of turbulence

Distribution of energy

Large-eddy simulation

Issues with current closure models

Discrete LES

Exact discrete stress

Space-time LES

Inductive bias

Conclusion

- Closure model  $M_\theta$  depends on parameters  $\theta$
- Learn  $\theta$  from high-fidelity data  $\mathcal{D}$ :

$$\min_{\theta} \mathbb{E}_{u \sim \mathcal{D}} \|M_\theta(\bar{u}) - C(u)\|^2$$

- Models that fit target data well can still be **unstable** when deployed in LES

*There are other commutators than  $C(u)$ .  
They cause the instabilities.*

## Learned LES

S. D. Agdestein

### Identify all commutators

- › from the filter  $\overline{(\cdot)}$
- › from the discretization  $\nabla_h$
- › from symmetry groups in the model  $M_\theta$

### Address all commutators

- › Eliminate them by choosing  $\overline{(\cdot)}$ ,  $\nabla_h$ , and  $M_\theta$  in a smart way
- › Account for the remaining ones by tuning the parameters  $\theta$

Exact discrete stress

The components of LES

Filtering

Divergence theorem

Burgers' equation

Discretization contribution

Discretization-aware closure

Incompressible Navier-Stokes

Take-away

Space-time LES

Inductive bias

Conclusion

# Divergence theorem

The mechanism powering the FVM

$$\partial_x^h u(x) = \frac{u\left(x + \frac{h}{2}\right) - u\left(x - \frac{h}{2}\right)}{h} = \frac{1}{h} \int_{x-h/2}^{x+h/2} \partial_y u(y) dy = \overline{\partial_x u}^h(x)$$

The discrete divergence  $\partial_x^h$  is induced by the FVM filter  $\overline{(\cdot)}^h$   
 $\implies$  **exact** discrete conservation laws for  $\bar{u}^h$

Learned LES

S. D. Agdestein

$$\partial_t u + \partial_x \sigma(u) = 0, \quad \sigma(u) = uu/2 - \nu \partial_x u$$

## Apply LES/FVM filters

$$\partial_t \bar{u}^{\Delta,h} + \partial_x^h \overline{\sigma(u)}^\Delta = 0$$

## Introduce numerical flux

$$\partial_t \bar{u}^{\Delta,h} + \partial_x^h \sigma^h(\bar{u}^{\Delta,h}) = -\partial_x^h \tau^{\Delta,h}(u)$$

## Unresolved discrete flux

$$\tau^{\Delta,h}(u) = \overline{\sigma(u)}^\Delta - \sigma^h(\bar{u}^{\Delta,h})$$

Space-time LES

Forward Euler is a filter

Space-time filter-swap

One new term

Results

Inductive bias

Conclusion

## Filter-swap in space (before)

$$\partial_x^h = \overline{(\cdot)^h} \circ \partial_x$$

## Filter-swap in time (new)

$$\bar{u}^\tau(t) := \frac{1}{\tau} \int_0^\tau u(t+s) ds$$

$$\partial_t^\tau u(t) := \frac{u(t+\tau) - u(t)}{\tau} = \overline{\partial_t u}^\tau(t)$$

*Forward Euler is a one-sided top-hat time filter.*

# Forward Euler is a filter

## The temporal filter-swap

Chord slope  $\partial_t^\tau u =$  mean of  $\partial_t u$  over the step

Agdestein, *Time integration as filtering: a space-time*

*discretization-aware LES formulation, DLES15*  
(2026)

## Filter the conservation law in space and time

$$\partial_t u + \partial_x \sigma(u) = 0$$

$$\implies \partial_t^\tau \bar{u}^h + \partial_x^h \overline{\sigma(u)^\tau} = 0$$

*Exact: forward Euler driven by the step-averaged flux  $\overline{\sigma(u)^\tau}$  reproduces  $\bar{u}^h$  at every time node – at any CFL number.*

## Space-time filter-swap

An exact fully discrete conservation law

One space-time cell: update = time-averaged fluxes through the faces

# The residual flux gains exactly one term

## Space-time decomposition of the closure target

$$\tau^{h,\tau}(u) := \overline{\sigma(u)^\tau} - \sigma^h(\bar{u}^h) = \underbrace{\tau_{\text{classic}}^h(u) + \tau_{\text{flux}}^h(u) + \tau_{\text{div}}^h(u)}_{\text{spatial terms (as before)}} + \underbrace{\tau_{\text{time}}^\tau(u)}_{:= \overline{\sigma(u)^\tau} - \sigma(u)}$$

*No temporal commutator appears: the new term is a pure flux time-quadrature error, shrinking with the order of the integrator.*

## Leading order: Lax-Wendroff diffusion

$$\tau_{\text{time}}^\tau(u) = \frac{\tau}{2} \partial_t \sigma(u) + \mathcal{O}(\tau^2) = -\frac{\tau}{2} (\sigma'(u))^2 \partial_x u + \mathcal{O}(\tau^2)$$

Eddy viscosity  $\frac{\tau}{2} (\sigma'(u))^2 \geq 0$ : **dissipative by construction** – the diffusion that stabilizes forward-Euler convection

Learned LES

S. D. Agdestein

Simulating turbulence

Discrete LES

Exact discrete stress

Space-time LES

Forward Euler is a filter

Space-time filter-swap

One new term

Results

Inductive bias

Conclusion

## Augment the discretization-aware Smagorinsky model

$$m^{h,\tau}(\cdot) := \underbrace{-\theta_h^2 h^2 |\partial_x^h \cdot| \partial_x^h \cdot}_{\text{spatial terms}} \underbrace{-\theta_\tau \tau (\sigma'(\cdot))^2 \partial_x^h \cdot}_{\text{temporal term}}$$

- One new coefficient  $\theta_\tau$ , with theoretical value  $\frac{1}{2}$  from the Lax-Wendroff expansion
- Fitted a priori by dissipation matching: the measured temporal dissipation is **linear in  $\tau$** , as predicted

# A priori: the temporal term dominates at practical CFL

Burgers turbulence, forward Euler, CFL 0.06 – 0.89

Learned LES

S. D. Agdestein

Simulating turbulence

Discrete LES

Exact discrete stress

Space-time LES

Forward Euler is a filter

Space-time filter-swap

One new term

Results

Inductive bias

Conclusion

- Spatial terms: fixed proportions, independent of the time step
- Temporal share grows with CFL: 0.19 → 0.59 (central flux)
- At practical CFL numbers, the **largest single term** is the one space-only formulations discard

# A posteriori: a CFL-robust closure

Coarse forward-Euler LES, error at final time

Learned LES

S. D. Agdestein

Simulating turbulence

Discrete LES

Exact discrete stress

Space-time LES

Forward Euler is a filter

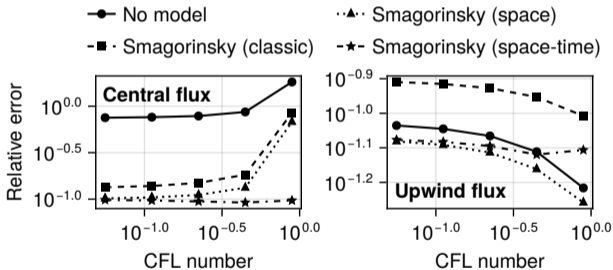

Space-time filter-swap

One new term

Results

Inductive bias

Conclusion

- Step-agnostic closures degrade as the CFL number grows
- The space-time-aware closure: **error independent of CFL** (0.092 – 0.098, central flux)
- Upwind flux over-dissipates; forward Euler partially cancels it

# Inductive bias and Reynolds-number generalization

- Reynolds-number generalization
- Out-of-distribution: Taylor-Green

- The stress *structure* is Reynolds-independent (flat a priori error), but the *dissipation calibration* drifts outside the training band
- Feeding one scalar,  $\text{Re}_\Delta = \Delta^2 \|\nabla \bar{u}\| / \nu$ , restores the calibration – for all three architectures alike

# Out-of-distribution: decaying Taylor-Green vortex

Trained closures applied unchanged to an unforced, transitional flow

- Laminar roll-up  $\rightarrow$  transition  $\rightarrow$  viscous decay: none of it appears in the forced training data
- Reuse is legitimate: the closures are amplitude- and Reynolds-invariant *in form*

Discrete LES

Exact discrete stress

Space-time LES

Inductive bias

Symmetries of the Navier-Stokes equations

Symmetries after discretization

Effect of symmetry-preserving models

Three routes to equivariance

Tensor basis neural network

Forced turbulence

Capacity

Reynolds-number generalization

Out-of-distribution: Taylor-Green

THRU-away

# Taylor-Green: partial generalization

## Learned LES

S. D. Agdestein

- Simulating turbulence
- Discrete LES
- Exact discrete stress
- Space-time LES
- Inductive bias
  - Symmetries of the Navier-Stokes equations
  - Symmetries after discretization
- Effect of symmetry-preserving models
- Three routes to equivariance
- Tensor basis neural network
- Forced turbulence
- Capacity
- Reynolds-number generalization
- Out-of-distribution: Taylor-Green

- Data-driven closures stay **stable and structurally faithful** through the transition
- But they carry a **flow-type over-dissipation** ( $\sim 2\times$ ) in this milder regime
- $Re_{\Delta}$  corrects the Reynolds share of the drift, not the flow-type share

# Take-away: does equivariance matter?

generalization

Out-of-distribution:  
Taylor-Green

Take-away

*Equivariance costs no accuracy: even the unconstrained MLP learns a near-equivariant map from isotropic data.*

*The inductive bias buys **parameter efficiency** and **reproducibility**, not a lower error floor: all pointwise closures saturate at the same optimal closure.*

*Reynolds-number generalization comes from the **Re $_{\Delta}$  input**, not from the architecture.*

# Conclusion

- 1 The problem: Simulation of turbulence
- 2 Discretization-consistent LES
- 3 Are we modeling the wrong stress tensor?
- 4 Time integration as filtering
- 5 Inductive bias and Reynolds-number generalization
- 6 Conclusion

Postlude

Thank you!

*The main problem in LES is the presence of commutator errors.*

*We identify new commutators in LES arising from the filter, discretization, and symmetry-groups.*

*We cancel out commutators through new filters, discrete formulations, and model architectures.*

*Exact expressions for the remaining commutators allow for producing unbiased training data for data-driven closure models.*

*This thesis offers a mathematically principled foundation for reducing the computational cost of turbulence simulations.*
